Thermodynamics of Einstein static Universe with boundary

G.E. Volovik¹

¹Landau Institute for Theoretical Physics, acad. Semyonov av., 1a, 142432, Chernogolovka, Russia (Dated: October 22, 2024)

The de Sitter state and the static Einstein Universe are the unique states, which have constant Ricci scalar curvature \mathcal{R} . Earlier it was shown that such unique symmetry of the de Sitter state leads to the special thermodynamic properties of this state, which are determined by the local temperature $T = 1/(\pi R)$, where R is the radius of the cosmological horizon. Then, what happens in static Universe? We consider the Einstein Universe, which has boundary. This can be the real physical boundary, or the border between two halves of the $R \times S^3$ Universe, if there is no contact between the halves. It appears that the static Einstein Universe with boundary is characterized by the same local temperature $T = 1/(\pi R)$ as the de Sitter state. The thermodynamics of the bounded Einstein Universe is also similar to that of de Sitter. If this Universe contains Zel'dovich stiff matter, there is the holographic connection between the entropy of the Universe and the surface entropy A/4G of the boundary. This means that in thermodynamics the physical boundary of the static Einstein Universe plays the role of the de Sitter cosmological horizon.

I. INTRODUCTION

Recently the possible connection between the entropy of the de Sitter state and the entropy of the static Einstein Universe has been discussed and it was found that these entropies can be parametrically equal. Here we consider the exact connection, in which the entropy of both states has the Bekenstein-Hawking value A/4G. The reason for that is the specific symmetry of both states, due to which the curvature is constant in space and time.

In the de Sitter state this is the symmetry of the space-time with respect to the combined translations, which in the Minkowski limit becomes the invariance of under translations. This

symmetry gives rise to the local thermodynamics of the de Sitter state, which is characterized by the local temperature.² This consideration is based on observation, that matter immersed in the de Sitter vacuum feels the de Sitter vacuum as the heat bath with the local temperature $T = H/\pi$, where H is the Hubble parameter, see also Ref.³. This temperature is twice the Gibbons-Hawking temperature, $T_{\rm GH} = H/2\pi$. But this leads to the local thermodynamics with the entropy density, which gives rise to the holographic connection between the bulk entropy of the Hubble volume and the surface Gibbons-Hawking entropy of the cosmological horizon, $S_{\rm bulk} = S_{\rm surface} = A/4G$.

In the static Einstein $R \times S^3$ Universe, the curvature is also constant in space and time. That is why one may expect that under certain conditions it may have the similar properties. One of the conditions is that the Einstein Universe must have the boundary. That is why we consider the half of the $R \times S^3$ Universe, as was actually considered by Einstein, see e.g. the review⁴. For the Universe with boundary we obtain the local temperature $T = 1/\pi R$, where R is the radius of the static Universe. This gives the holographic connection between the bulk entropy and the surface entropy A/4G of the boundary, which plays the role of the cosmological horizon. This is valid for the static Universe, which contains the Zel'dovich stiff matter with the same temperature.

II. STATIC UNIVERSE AND DE SITTER

A. Equilibrium conditions

We consider the gravitational degrees of freedom in the same way as the matter degrees of freedom. We introduce the stress-energy tensor for gravity in the same way as for matter and for vacuum energy, i.e. via the variation of the corresponding part of the action over the metric:

$$\delta S = \frac{1}{2} \int d^4x \sqrt{-g} \left(T^M_{\mu\nu} + T^{\Lambda}_{\mu\nu} + T^G_{\mu\nu} \right) \delta g^{\mu\nu} \tag{1}$$

Here $T_{\mu\nu}^M$, $T_{\mu\nu}^{\Lambda}$ and $T_{\mu\nu}^G$ are stress-energy tensors of correspondingly matter, vacuum energy and gravity. In this approach the total stress-energy tensor is zero:

$$T_{\mu\nu} = T_{\mu\nu}^M + T_{\mu\nu}^\Lambda + T_{\mu\nu}^G = 0, \qquad (2)$$

and thus the conservation of energy and momentum is automatically fulfilled: $T^{\mu\nu}_{,\nu}=T^{\mu\nu}_{;\nu}=0$.

For de Sitter state and for static Einstein Universe the gravitational part $T_{\mu\nu}^G$ of the stress-energy tensor is expressed via the Ricci scalar curvature \mathcal{R} . That is why the Eq.(2) can be written in terms of the energy densities and partial pressures of the corresponding components (see Eq.(29.38) in Ref.⁵):

$$\rho = \rho_M + \rho_\Lambda + \rho_R = 0 \,, \tag{3}$$

$$P = P_M + P_\Lambda + P_R = 0. (4)$$

Here $P_M = w_M \rho_M$ is the equation of state of matter; $P_{\Lambda} = -\rho_{\Lambda}$ is the equation of state of the dark energy. The quantity ρ_R is the energy density stored in the scalar curvature and $P_R = w_R \rho_R$ is the partial pressure related to the space curvature. The equation of state w_R for gravity have different values in de Sitter and in Einstein Universe.

The equation (3) means the gravineutrality, which is the analogue of electroneutrality.⁵ The equation (4) is the condition of the absence of external pressure, in which case the partial pressures of different components cancel each other.

B. Equilibrium conditions for de Sitter

For de Sitter state the gravitational energy density and the corresponding partial pressure are:

$$\rho_R = -\frac{1}{2}K\mathcal{R} = -6KH^2\,,\tag{5}$$

$$P_R = -\frac{d(\rho_R V)}{dV} = -\rho_R. \tag{6}$$

Here H is the Hubble parameter and K is the gravitational coupling:

$$K = \frac{1}{16\pi G} \,. \tag{7}$$

In Eq. (6) we take into account that the energy of the vacuum in the arbitrary volume V is proportional to V. This equation demonstrates that the equation of state of the gravitational component of de Sitter is the same as equation of state of the dark energy:

$$w_R = w_\Lambda = -1. (8)$$

Since de Sitter does not contain matter, the equilibrium conditions for de Sitter are

$$\rho = \rho_{\Lambda} + \rho_{R} = 0 , P = P_{\Lambda} + P_{R} = 0.$$
(9)

These conditions give $\rho_{\Lambda} = 6KH^2$.

C. Equilibrium conditions for static Universe

As distinct from de Sitter, in static Universe the equation of state for gravity is $w_R = -1/3$:

$$\rho_R = -K\mathcal{R} = -\frac{6K}{R^2},\tag{10}$$

$$P_R = -\frac{d(\rho_R V)}{dV} = -\frac{1}{3}\rho_R = \frac{2K}{R^2}.$$
 (11)

Here we take into account that the volume of the static Universe is proportional to R^3 , where R is the radius of the Universe, while $\rho_R \propto 1/R^2$.

Then the equilibrium conditions (3) and (4) give the following matter density and vacuum energy density in the static Universe:

$$\rho_M = \frac{2}{3(1+w_M)} K \mathcal{R} \,, \tag{12}$$

$$\rho_M + p_M = \frac{2}{3}K\mathcal{R} = \frac{4K}{R^2} \,, \tag{13}$$

$$\rho_{\Lambda} = K\mathcal{R} \left(1 - \frac{2}{3(1 + w_M)} \right) . \tag{14}$$

D. Particular states of static Universe

It was shown in Ref.², that the thermodynamics of the de Sitter state has some properties of Zel'dovich stiff matter with $w_M = 1$. For the static Universe with $w_M = 1$, one has the following relation between the vacuum energy density and the radius R of this Universe:

$$\rho_{\Lambda}(w_M = 1) = 2\rho_M = \frac{2}{3}K\mathcal{R} = \frac{1}{4\pi GR^2}.$$
(15)

In case of the cold matter with $w_M = 0$:

$$\rho_{\Lambda}(w_M = 0) = \frac{1}{2}\rho_M = \frac{1}{3}K\mathcal{R} = \frac{1}{8\pi GR^2}.$$
 (16)

The special case is $w_M = -1/3$, at which the equation of state for matter is the same as the equation of state for curvature, $w_M = w_R = -1/3$. In the expanding Universe this equation of states is on the border between deceleration and acceleration, see e.g. Ref.⁶. In the static Einstein Universe this corresponds to the absence of the dark energy component:^{7,8}

$$\rho_{\Lambda}(w_M = w_R = -1/3) = 0. \tag{17}$$

This is similar two the 2-component situation in de Sitter in Eq.(8), where the matter component is absent.

III. CREATION OF MASSIVE PARTICLES AND LOCAL TEMPERATURE

A. Creation of massive particles in the Universe with boundary

In the elliptical Universe, the metric is given by:

$$ds^{2} = -dt^{2} + \frac{dr^{2}}{1 - \frac{r^{2}}{R^{2}}} + r^{2}d\Omega^{2},$$
(18)

which can be compared with the de Sitter metric with R = 1/H:

$$ds^{2} = -dt^{2} \left(1 - \frac{r^{2}}{R^{2}} \right) + \frac{dr^{2}}{1 - \frac{r^{2}}{R^{2}}} + r^{2} d\Omega^{2}.$$
 (19)

Both metrics have coordinate singularity at r = R. This singularity can be either unphysical, which can be removed by the proper coordinate transformation, or physical if it serves as the boundary of the Universe. Here we consider the latter case – the static Einstein Universe with the boundary at the equator. The volume of this Universe is half of the total volume V of the spherical $R \times S^3$ Universe:

$$V_{\frac{1}{2}} = 4\pi \int_0^R dr \frac{r^2}{\sqrt{1 - \frac{r^2}{R^2}}} = \pi^2 R^3 = \frac{V}{2}.$$
 (20)

Let us compare the creation of massive particles in the Einstein and de Sitter Universes. In the semiclassical limit the tunneling trajectory $p_r(r)$ of particle with mass M in the Einstein Universe is determined by equation:

$$E^2 = g^{rr}p_r^2 + M^2 \ , \ g^{rr} = 1 - \frac{r^2}{R^2} \ ,$$
 (21)

while in the static de Sitter one has

$$\frac{E^2}{1 - \frac{r^2}{R^2}} = g^{rr} p_r^2 + M^2 , \ g^{rr} = 1 - \frac{r^2}{R^2}.$$
 (22)

For E=0, this would correspond to the creation of particle with mass M from the vacuum. But for E=0 one obtains the same trajectory in both Universes:

$$p_r(r) = i \frac{M}{\sqrt{1 - \frac{r^2}{R^2}}} \,. \tag{23}$$

Since the rate of particle creation is given by the imaginary part of the action along this trajectory, then in the WKB approximation one obtains the following creation rate:

$$w \sim \exp(-2\text{Im }S) = \exp\left(-2M \int_0^R \frac{dr}{\sqrt{1 - \frac{r^2}{R^2}}}\right) = \exp(-\pi MR).$$
 (24)

The rate is the same as the rate of particle creation in the thermal bath with temperature $T = 1/(\pi R)$ in the flat space:

$$w \sim \exp\left(-\frac{M}{T}\right) , T = \frac{1}{\pi R}.$$
 (25)

For the de Sitter state, this have been obtained using the Painleve-Gullstrand metric, which has no coordinate singularity at the horizon. This is also the natural result in the static de Sitter coordinates, since the trajectory can be extended to the region behind the horizon, where the momentum $p_r(r)$ becomes real.

For the static Einstein Universe this is problematic, since the S^3 space has no boundary, and the region with r > R simply does not exist. But this becomes possible if the region with r > R is somehow available. Here we assume that such travel to the region r > R is possible if we consider the static Universe at r < R as the part of the larger Universe, where in the region r > R the metric has opposite signature. In this case we obtain the same Eq.(24) for the creation rate, and thus the same temperature $T = 1/\pi R$ of the static Universe. This temperature is fully determined by the radius R of the Universe regardless of the equation of state w_M for matter. In this approach, the static Einstein Universe represents the half of the $R \times S^3$ Universe. It has the boundary at r = R, which is analogous to the cosmological horizon of the de Sitter state.

If this is true, then the creation of particles would provide the instability of the static Universe in the same way as the creation of particles by the de Sitter heat bath leads to the decay of the de Sitter Universe in Ref.².

B. Pair creation in two half-Universes

The same temperature $T = 1/\pi R$ can be obtained using the picture in which the closed $R \times S^3$ Universe with metric

$$dl^2 = d\chi^2 + \sin^2 \chi d\Omega^2 \,, (26)$$

splits into two half-Universes with the boundary between them. In this case the pair of fermions (particle and hole) can be created: the hole at r=0 (at $\chi=0$) and particle also at r=0 but at the mirror point, i.e. at $\chi=\pi$. In terms of the spherical coordinates of the 3-sphere, the pair creation rate is given by imaginary part of the action $S=M\int ds=M\int \sqrt{dt^2-R^2d\chi^2}$, when particle and hole are created at r=0, and then particle moves to the opposite point.

The rate of pair creation is:

$$w \sim \exp(-2\text{Im }S) = \exp\left(-2MR\int_0^{\pi} d\chi\right) = \exp(-2\pi MR) = \exp(-2M/T).$$
 (27)

Since two particles are created coherently, this again corresponds to temperature $T = 1/\pi R$.

IV. THERMODYNAMICS OF STATIC UNIVERSE

Eq.(25) suggests that the static Einstein half-Universe looks as the heat bath for matter in the same way as the de Sitter Universe. Both have the constant curvature and both are characterized by the local temperature $T = 1/(\pi R)$, with R = 1/H being the Hubble radius in the de Sitter case. Then, as in the de Sitter case, the local temperature allows us to discuss the thermodynamics of this static Universe, where the vacuum energy density can be expressed in terms of the local temperature.

There are only two possible states where such thermodynamics can be considered. These are the dust matter, which does not have thermal properties, and the Zel'dovich stiff matter, which has the same temperature as the Λ -component, $T = 1/(\pi R)$.

A. Einstein Universe with cold matter

For the Einstein Universe with cold matter one has:

$$\rho_{\Lambda} = \frac{\pi}{8G} T^2 \,, \tag{28}$$

and

$$s_{\Lambda} = \frac{\pi}{4G}T = \frac{1}{4GR} \,. \tag{29}$$

Taking into account the vacuum temperature $T = 1/\pi R$, one obtains:

$$s_{\Lambda}T = \frac{\pi}{4G}T^2 = \frac{1}{4\pi GR^2} = \frac{4K}{R^2} = \rho_M + p_M.$$
 (30)

This gives the Gibbs-Duhem relation for the thermodynamics of static Universe with cold dark matter:

$$s_{\Lambda}T = \rho_M + p_M = (\rho_M + \rho_{\Lambda}) + (p_M + p_{\Lambda}). \tag{31}$$

This suggests that the vacuum of this Universe does provide the nonzero temperature and entropy. But the exchange between the "thermal" vacuum and cold matter will warm the matter and destroy the static solution. The only possibility of the stabilization of the static Universe is the stiff matter, which has the same temperature as the heat bath and the same T^2 dependence as the dark energy.

B. Einstein Universe with stiff Zel'dovich matter

Stiff matter is in the thermal equilibrium with the dark energy, if it has the same temperature $T = 1/\pi R$. The dark energy density in Eq.(15) expressed via this temperature is

$$\rho_{\Lambda} = \frac{\pi}{4G} T^2 \,. \tag{32}$$

Note that the total energy density, which includes the energy density of stiff matter contains the extra factor 3/2, but we are interested here in the dark energy component.

Then, the Eq.(32) gives the following entropy density of the dark component:

$$s_{\Lambda} = \frac{\pi}{2G}T = \frac{1}{2GR} \,. \tag{33}$$

V. HOLOGRAPHIC BULK-BOUNDARY CONNECTION

A. Bounded Einstein Universe

Let us consider the coordinates of round metric on the 3-sphere, which explicitly demonstrate the uniform nature of the static Universe:

$$dl^2 = d\eta^2 + \sin^2 \eta \, d\xi_1^2 + \cos^2 \eta \, d\xi_2^2 \,, \tag{34}$$

where $0 < \eta < \pi/2$ and $0 < \xi_1, \xi_2 < 2\pi$.

The volume V of the Universe is:

$$V = 2\pi^2 R^3 \,. \tag{35}$$

This Universe is also characterized by the 2D "equator" at $\eta = \pi/4$, which area A is:

$$A = 2\pi^2 R^2. \tag{36}$$

Let us recall that the intersection of a 3D-sphere with a three-dimensional hyperplane is a 2D-sphere. As the 3D-sphere moves through the 3D-hyperplane, the intersection represents the growing 2D-sphere that reaches its maximal size and then shrinks. The maximum size corresponds to the "equator" with the area A in Eq.(36).

We consider the half of the static Universe – the half of the 3D sphere, which is bounded by the equator at $\eta = \pi/4$. Let us show that in such Universe there is the analog of the holographic bulk-surface connection, which is similar to that in the de Sitter state. Now it is the connection between the entropy of the bulk coming from the dark energy and the entropy related to the boundary of the Universe, which plays the role of the cosmological horizon.

B. Holographic connection for half-Universe with stiff matter

In case of Zel'dovich stiff matter, from Eq.(33) for the local entropy of dark energy one obtains the total dark entropy of the bounded Universe:

$$S_{\Lambda} = s_{\Lambda} V_{\frac{1}{2}} = \frac{1}{2GR} \pi^2 R^3 = \frac{\pi^2 R^2}{2G} = \frac{A}{4G}.$$
 (37)

The entropy is fully expressed in terms of the area of the boundary, and it obeys the same holographic area law as the entropy of the Hubble volume in de Sitter Universe. But now the role of the cosmological horizon is played by the boundary of the static Universe.

This actually supports the possible connection between Bekenstein-Hawking entropy of the 2+1 de Sitter horizon that of static Einstein $R \times S^2$ Universe.¹ But the holographic law in Eq.(37) is valid only for the half-Universe with stiff matter. For the $Z \times S^3$ Universe with cold matter one may also try to write the connection between the entropy in the full volume via the area of equator:

$$S_{\Lambda} = s_{\Lambda} V = \frac{1}{4GR} \, 2\pi^2 R^3 = \frac{A}{4G} \,. \tag{38}$$

But this is not valid, because A is the maximal area instead of the area of the boundary of the Universe. The $Z \times S^3$ Universe has no boundaries, and thus one has T = 0 and $s_{\Lambda} = 0$.

VI. CONCLUSION

The local temperature, $T = 1/\pi R$, and holographic connection for the entropy, S = A/4G, make sense in the static Einstein Universe if the Universe has the physical boundary at r = R, where the spatial metric in Eq.(18) has coordinate singularity. This corresponds to the half of the Einstein Universe, where the coordinate singularity represents the real boundary. Such boundary can be also considered as the border between two halves of the full Universe, if there are no contacts between the two sub-Universes.

It is interesting that the same temperature and the same holographic law take place for the de Sitter state, where the role of the boundary is played by the cosmological horizon with R = 1/H. The reason is that both states can be described by the same spatial part of metric. In both states the curvature is constant in space and time, and serves as the thermodynamic variable together with the inverse Newton "constant", which is thermodynamically conjugate to curvature. Moreover, in both states the important role is played by the Zel'dovich stiff matter with the same temperature $T = 1/\pi R$.

This observation confirms the connection between the entropy of the Bekenstein-Hawking horizon in the 2+1 de Sitter and the entropy of the static Einstein $R \times S^2$ universe.¹ But instead of parametric agreement, we have an exact match, which suggests that our approach may make sense.

In the Universe without boundaries such thermodynamics does not look promising, although the connection is possible between the local temperature and the externally fixed temperature in Ref.⁹.
